Serotonin (5-HT) is one of the main neurotransmitters in the human central nervous system and peripheral nervous system. It helps regulate appetite, memory, cognition and mood through serotonin receptors (5-HTR).

A group of international scientists recently made a breakthrough in understanding the structure and function of serotonin receptors. This is the first time researchers have reported the structures of the 5-HT<sub>4</sub>, 5-HT<sub>6</sub>, and 5-HT<sub>7</sub> receptors, and resolved the structures of all 12 5-HT receptor subtypes.

The study was published online in *Molecular Cell* on June 16.

Researchers led by H. Eric Xu from the Shanghai Institute of Materia Medica (SIMM) of the Chinese Academy of Sciences, in collaboration with researchers from Zhejiang University and the University of Copenhagen, systematically revealed the structural basis for the recognition of serotonin receptor subtypes by the small-molecule ligands 5-HT and 5-CT. They also elucidated the [molecular mechanism](#) for the selective coupling of G<sub>s</sub> and G<sub>i</sub> proteins by serotonin receptors.

The serotonin receptor family is one of the most complex subfamilies in the G-protein-coupled receptor (GPCR) superfamily and contains 12 subtypes. Different receptor subtypes play different physiological roles in the human body and are coupled with different kinds of G proteins. Among them, the 5-HT<sub>4</sub>, 5-HT<sub>6</sub>, and 5-HT<sub>7</sub> receptors are mainly coupled to downstream G<sub>s</sub> proteins, and the 5-HT<sub>1</sub> and 5-HT<sub>5</sub> receptors are mainly coupled to downstream G<sub>i</sub> proteins.

Through structural comparison of these three  $G_s$ -coupled serotonin receptors to the  $G_{i/o}$ -coupled serotonin receptors, and to 19 additional  $G_s$ - and  $G_{i/o}$ -coupled class A receptor structures, the team uncovered a class-wide G protein selectivity mechanism that uses TM5 and TM6 switches.

"These findings advance the fundamental understanding of how serotonin receptors, the largest subfamily of class A GPCRs activated by the same endogenous ligand, create their wide diversity of cellular responses," said Xu, corresponding author of the study.

Furthermore, these structural insights into ligand recognition provide the foundation for rational structure-based drug design targeting the 5-HT<sub>4</sub>, 5-HT<sub>6</sub>, and 5-HT<sub>7</sub> receptors. These insights also help clarify how to achieve ligand selectivity within the complex serotonergic system.

The achievement not only revealed the molecular mechanism of the selective coupling of G-proteins by class A GPCRs but also filled in the last gap in the [structural analysis](#) of 5-HT family receptors, according to the researchers.

These systematic studies of serotonin receptors have greatly enriched our understanding of the structure and function of the serotonin system. Since depression, schizophrenia, and migraine may be linked to [serotonin](#), this research may also contribute to treatments for these conditions.
