

New method enables efficient sample preparation for single-cell proteomics

August 4 2022

Efficient Sample Preparation for Single-cell Proteomics with Water Droplet-in-Oil Digestion

Single-cell proteomics is an important analytical tool in biomedical research

Cancer genomics

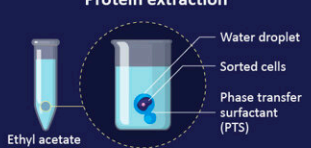

Cell differentiation

Tissue development

Can the low sample recovery and throughput rates of current in-solution digestion (ISD) method be improved?

New water droplet-in-oil digestion (WinO)-based sample preparation for proteomics

Protein extraction

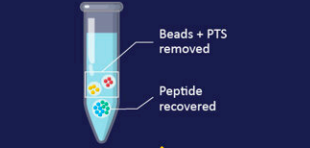

Ethyl acetate

Water droplet

Sorted cells

Phase transfer surfactant (PTS)

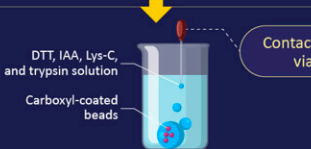

Beads + PTS removed

Beads + PTS removed

Peptide recovered

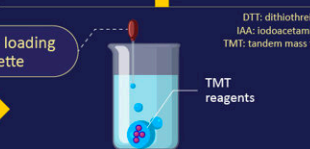

Reduction, alkylation, and digestion

DTT, IAA, Lys-C, and trypsin solution

Carboxyl-coated beads

Peptide labeling

Contactless loading via pipette

TMT reagents

✔ Low sample-container contact area

✔ 10x peptide/protein recovery

✔ 462 proteins quantified

✔ Strong correlation between proteome profiles obtained with WinO and ISD methods

The WinO method reduces sample loss and increases the sensitivity of protein identification, making it highly suitable for single-cell proteomics

Water Droplet-in-Oil Digestion Method for Single-Cell Proteomics

The proteins that make up our cells hold within an entire world of information, which, when unlocked, can give us insights into the origins of many essential biological phenomena. This information is gathered using an analytical technique known as "single-cell proteomics," in which a single-cell analysis is performed to observe the characteristics of individual cells at their protein level. Over the years, scientists have used

single-cell proteomics in the fields of cancer genomics, cell differentiation, and tissue development. However, current proteomics techniques suffer from low recovery rate of protein samples, low throughput, and lack of versatility.

Fortunately, a team of researchers from Japan and U.S. led by Assistant Professor Takeshi Masuda from Kumamoto University in Japan have found a solution to these problems. In a recent study made available online on 11 July 2022 and published in *Analytical Chemistry* on 26 July 2022, the team introduced a simple yet highly efficient sample preparation method for single-cell proteomics called "water droplet-in-oil method" (WinO). The technique uses the immiscibility of water with oil/[organic solvent](#) to its advantage to prepare protein samples with minimum loss and increased chances of sample recovery.

"To make single cell-proteomics more efficient, we either need to amplify the protein sample or make sure none of it is lost during sample preparation. Since we didn't have the means to do the former, it was crucial that we reduced absorption losses during sample preparation steps like sample transfer," explains Dr. Masuda. "The WinO technique not only reduces sample loss through adsorption but also provides better throughput when compared with conventional methods."

For the WinO process, the team first prepared an extraction buffer by mixing one microliter of water with phase transfer surfactants (which increase the solubility of hydrophobic proteins) and hydrophobic carboxyl-coated nanomagnetic beads. This mixture was then dropped into 50 microliters of ethyl acetate.

The next step was protein extraction, which was performed by adding cell droplets from the cell sorter to the ethyl acetate-water droplet combo and spinning it in a centrifuge to allow the protein to accumulate within the water droplet. After the extraction, the sample was digested using a

protein enzyme, Lys-C, and labeled using a "tandem mass tag" reagent. The extracted-digested-labeled sample was then purified and recovered for single-cell analysis and [proteomic](#) profiles.

To compare the efficacy of the WinO method against conventional methods, the team also prepared samples using the standard in-solution digestion (ISD) method and carried out proteomic analysis. They found that the WinO method led to a 10-fold increase in protein and peptide recovery compared to ISD. This remarkable improvement was attributed to a reduced contact area between the extraction solution and the sample container.

To analyze the sensitivity of both methods, the team also compared the obtained proteomic profiles. They observed a high correlation between proteomic profiles obtained for 100 cells using WinO and that for 10,000 cells using ISD. Furthermore, the team successfully quantified 462 proteins using WinO, demonstrating that it provided a much higher throughput and extraction efficiency than conventional techniques.

The enhanced protein recovery and identification ability provided by WinO could enable a closer look at the protein expression of cancer [cells](#) and a better understanding of the mechanisms underlying anticancer drug resistance. Further, WinO can be semi-automated using a liquid handling robot, making it suitable for high-speed, large-capacity processing of samples. "Our research could allow scientists to perform proteomics on rare and limited sample amounts as well as provide a novel perspective on [protein](#) expression, opening up possibilities for discovering new biological phenomena," concludes Dr. Masuda.
