

What is the smallest planet? (It's not Pluto.)

Taking a closer look at planet sizes.

As elementary schoolers, we learned the order of the planets. Maybe your teacher even had a snappy mnemonic like "My Very Educated Mother Just Served Us Nine Pizzas" or "My Very Educated Mother Just Served Us Nachos" after Pluto was axed from the planetary lineup.

The International Astronomical Union even formally recognizes the latter mnemonic device, while also pointing out the five [dwarf planets](#) that exist among the eight major ones.

The order of the planets is an easy one to remember, but what about the size of the planets? Here is a breakdown of the size of the planets in our solar system.

What is the smallest planet?

The smallest planet in our solar system is Mercury. The planet is about 1/3 of the width of Earth with a radius of 1,516 miles. Earth's moon has a radius of just over 1,000 miles.

Scientists determine the size of planets by measuring how big it is against the sky, BBC Science Focus reports. This angular diameter is combined with its distance (based on its orbit around the sun) to calculate size.

The second smallest planet is Mars, which is about half the size of the Earth with a 2,106-mile radius.

Next is Venus, which is only slightly smaller than Earth. Venus' radius is 3,760 miles.

What is the biggest planet?

The largest planet is Jupiter, according to the National Aeronautics and Space Administration. Jupiter has a radius of 43,441 miles and is 11 times the size of Earth.

The planets in order of size, listed from biggest to smallest:

- Jupiter: 43,441-mile radius
- Saturn: 36,184-mile radius
- Uranus: 15,759-mile radius
- Neptune: 15,299-mile radius
- Earth: 3,959-mile radius
- Venus: 3,760-mile radius
- Mars: 2,106-mile radius
- Mercury: 1,516-mile radius

Which planet is closest to the sun?

Mercury is not only the smallest planet but also closest to the sun. Mercury is nearly 36 million miles away from the sun, or 57.9 million kilometers, NASA reports.

The Earth is about 93 million miles from the sun—a number you may have had to memorize in science class. The farthest planet is Neptune at approximately 2.8 billion miles from the sun.

But while Mercury is closest to the sun, Venus is actually our [solar system](#)'s hottest planet. Surface temperatures on Venus are 900 degrees Fahrenheit, according to NASA. Mercury still clocks in at a maximum of 800 degrees during the day, but temperatures can drop to negative 290 degrees because the planet has no atmosphere.

Instead of an atmosphere, Mercury has a thin exposure made of atoms that use [solar wind](#) and strike meteoroids to blast off the surface, NASA writes.

Is Mercury smaller than Pluto?

Mercury is bigger than Pluto, but it's still considered the smallest planet because of Pluto's designation as a dwarf planet.

In 2006, the IAU determined Pluto did not meet the qualifications to be a planet because it doesn't clear its orbital path like the other planets do.

Mercury's diameter is bigger than [dwarf planet](#) Pluto, which has a diameter of only about 1,473 miles, while Mercury's is 3,030.
