

GMO skeptics still distrust big agriculture's climate pitch

November 13 2022, by Juliette MICHEL

Agrochemical companies have long developed seeds designed to thrive in particular local conditions.

As a changing climate intensifies extreme weather, agricultural multinationals are hyping the ability of genetically modified crops to

boost yields when facing drought, heat or even heavy rainfall.

But skeptics of engineered foods, or genetically modified organisms (GMOs), still aren't buying it.

"I don't see why we should evolve our views when they're still doing the same things," said Bill Freese, science director at the non-profit Center for Food Safety, criticizing the "dramatically increased toxic herbicide use" following the proliferation of GMOs.

Seeds designed to thrive in specific local conditions have been developed for centuries through conventional breeding, by crossing together plants with relevant characteristics and selecting the desired offspring.

But as more severe weather creates hostile growing conditions for conventional seeds, companies such as Bayer/Monsanto, Corteva and Syngenta are promoting GMOs as more efficient.

And newer technologies can reduce development times for these heartier varieties "by many years" compared with traditional crop modification techniques, according to a spokesperson for Germany's Bayer.

"Drought tolerance is a complex trait involving many genes," the spokesperson said. "Therefore, the ability to develop drought-tolerant traits through classic breeding methods such as crossbreeding is limited."

Longtime GMO critics say they are open to new approaches but are not sold on the latest industry pitch, viewing conventional seed products as safer and with fewer environmental drawbacks.

"How many times have we read that we won't be able to feed the world by 2050 unless we have GMOs?" said Freese, referring to the argument of GMO proponents that genetically modified crops will be necessary to

produce enough food for a [growing population](#) on a warming planet.

But for Freese, that claim is "just a really effective smoke screen put on by the pesticide and seeds conglomerates to put a good face on this new technology."

US company Corteva said it, too, is focused on "new breeding technologies such as gene editing" to "take advantage of the genetic diversity that already exists within the plant's DNA" when it comes to creating new seed types.

Such GMO products can help normalize a crop's performance, even if extreme moisture from rain or flooding promotes the spread of fungus or pests, companies say.

In July, the World Economic Forum highlighted the potential for GMOs to help reduce [greenhouse gas emissions](#) by creating breeds that remove more carbon dioxide than conventionally grown crops.

Safety, environmental concerns

Many American growers favor GMO options because, while more costly, they require less human labor, Freese said.

More than 90 percent of the corn, cotton and soybeans grown in the United States is currently genetically modified to withstand herbicides and/or insects, according to US government figures.

Farmers have been growing corn meant to tolerate drought since 2011. Whether or not this trait is achieved with traditional breeding or with GMO seeds, the resulting plants are then usually combined with GMOs that can withstand herbicides.

"They told us in the '70s and '80s that GMOs were going to be more nutritious, fix the nitrogen level, withstand everything," said Michael Hansen, a senior scientist at Consumer Reports. "What did we see? Mainly herbicide-tolerant crops."

Dana Perls, senior food and agricultural program manager at environmental network Friends of the Earth, said GMOs "go hand in hand with harsh chemicals that perpetuate pesticide pollution," harming insect populations, [soil health](#) and water quality.

Perls acknowledged "incredible advances" in mapping and manipulating genetic material, but said scientists "are still quite limited in our understanding of the functioning of the incredible complexity of life, both within a single organism and within ecosystems."

For now, she advocates for regulatory oversight of new GMO technology "rooted in a precautionary approach."

Andrew Smith of Rodale Institute said using GMOs to help crops withstand droughts and other extreme conditions is "nearsighted" unless the health of the soil is ensured.

Smith favors agricultural practices such as rotating crops, limiting chemical inputs and reducing soil tillage. Such techniques, known as regenerative agriculture, leads to healthier soil able to retain more water.

"It's a strategy to mitigate climate change," said Smith.
