

Researchers discover jet streams in Mars' magnetosheath

June 9 2023, by Sara-Lena Brännström

MAVEN spacecraft has been in orbit around Mars for almost ten years. Credit: NASA/GSFC

A research team from Umeå University and the Swedish Institute of Space Physics in Kiruna has discovered jet streams in the magnetosheath of Mars using data collected by NASA's MAVEN spacecraft. This is the first time such a jet has been found in the magnetosheath of a planet other than Earth. The results are published in the journal *Science*

Advances.

A magnetosheath jet is a clump of flowing plasma in the magnetosheath. It is distinguished by being faster or denser than its surroundings, sometimes both faster and denser. The magnetosheath is the part of space where the [solar wind](#) is forced to flow around a planet.

"Jet streams in magnetosheaths have been seen near Earth for 25 years and we were really curious if they could be found elsewhere," says Herbert Gunell, Associate Professor at Umeå University, who led the study.

NASA's MAVEN spacecraft has been in orbit around Mars since 2014 to study the Martian atmosphere and its interaction with the solar wind.

Observation location. Positions of the MAVEN spacecraft in Mars Solar Orbital (MSO) coordinates during the three observations. Spacecraft positions projected onto (A) the x - y , (B) the x - z , and (C) the y - z plane. (D) Spacecraft positions in a cylindrical coordinate system, where the vertical axis represents the distance to the MSO x axis. The arrows show the direction of the velocity component in the plane of each panel. The velocity is normalized so that all arrows have the same length. The component in the y - z plane (C) is substantially smaller than the other components. The dashed and solid lines show a model bow shock (27) for two different parameter sets. The spacecraft moves about 100 to 200 km during a jet

observation, which is smaller than the symbol that marks the positions in the figure. Credit: *Science Advances* (2023). DOI: 10.1126/sciadv.adg5703

"Before MAVEN, only around Earth did we have satellites with instruments fast enough to detect jets. But it was not obvious that we would find them on Mars, as there are important differences between the two planets. For example, Mars is smaller than Earth and lacks a global magnetic field, so the magnetosheath on Mars is much smaller than on Earth. Despite these differences, we now know that Mars also has magnetosheath jets," says Herbert Gunell.

"We have already seen that magnetosheath jets generate waves and that they can move through the entire magnetosheath and into the region of stronger magnetic fields further down. We have just discovered that they exist on Mars, and it will be exciting to find out more about them and the role they play in the interaction between Mars and the solar wind."
