

Recent advances in nickel-based catalysts for electrochemical reduction of carbon dioxide

September 20 2023

In this review, the research progress of the Nickel-Based catalyst towards CO₂ reduction reaction (CO₂RR) was summarized, combined with a revisit towards the current reaction mechanism, aiming to achieving a systemic picture towards structure-performance relationship. In a paper published in *Advanced Sensor and Energy Materials*, an international team of scientists reviewed recent advances in nickel-based catalysts for electrochemical reduction of carbon dioxide. The relevant CO₂RR mechanisms are first discussed in detail.

Following this, several typical Ni-based catalysts including Ni-based complexes catalysts, nanoparticles and alloys, Ni-based compounds, and atomically dispersed Ni catalysts are summarized. The preparation strategies for industrial-level electrocatalysts are also highlighted in this review.

Finally, the opportunities, challenges, and future outlooks of CO₂RR technology are summarized. This review introduces the recent advances and frontiers of nickel-based CO₂RR catalysts, which enlightens the path for further exploration of highly efficient CO₂RR electrocatalysts. This study is led by Meiling Xiao from State Key Laboratory of Electroanalytical Chemistry, Changchun Institute of Applied Chemistry.

The study is led by Meiling Xiao (State Key Laboratory of Electroanalytical Chemistry, Changchun Institute of Applied Chemistry, China).

Carbon dioxide is a notorious greenhouse gas, contributing to energy scarcity and the greenhouse effect. By employing techniques for direct capture, conversion, and utilization, it is possible to effectively reduce the levels of [carbon dioxide](#) in the atmosphere. CO₂ can be transformed into valuable materials through various methods, including electrochemistry, photochemistry, biochemistry, and thermochemistry.

Because of the ability to store intermittent renewable energy with nearly zero emissions, electrochemical CO₂ reduction is an intriguing field.

Meanwhile, CO₂ reduction reaction (CO₂RR) stands out due to its high reaction rate and its flexible and controllable process, making it the most promising avenue for industrial-scale renewable energy storage.

Despite considerable efforts, the activation of inert linear CO₂ molecules remains a significant challenge due to thermodynamic stability and sluggish reaction kinetics, thereby impacting the CO₂ [reduction reaction](#).

On the other hand, a wide range of possible products can be formed during practical CO₂ reduction processes, such as carbon monoxide, formate, methanol, ethanol, ethylene, and hydrocarbons, reflecting the diverse reaction pathways of CO₂ reduction that exhibit significant variations under different conditions.

Given the fact that many reaction pathways have similar theoretical initiation potentials, simultaneous production of different products can occur during the reaction, resulting in poor selectivity. Moreover, the competitive hydrogen evolution reaction (HER) also leads to low Faradaic efficiencies (FE) for specific products.

Therefore, the exploration of catalysts suitable for CO₂ reduction is of utmost importance. Since the pioneering work by Hori and colleagues in 1985 on electroreduction products, researchers have tested various metallic materials. Over the past few decades, precious metals like gold, platinum, silver, and palladium have exhibited excellent CO₂RR performance.

However, their low abundance and high cost pose challenges for industrial implementation. Hence, non-precious metals with satisfactory selectivity and high FE have been extensively studied as low-cost catalysts. These [electrode materials](#) include a wide range of metals such as copper, zinc, tin, bismuth, and nickel.

Among these catalysts with metal atoms as active centers, catalytic materials with Ni sites exhibit more prominent advantages. As a popular earth-abundant metal belonging to Group VIII-B, Ni is regarded as an ideal substituent for precious metals in the design of CO₂RR catalysts, due to a wide variety of Ni valences from 0 to +4.

The rich redox properties coupled with various coordination geometries make rational design of ligand frameworks possible to coordinate with the Ni center, imparting specific catalytic functions to nickel-based materials. Additionally, Nickel has been identified as an active center in natural enzymes, exemplified by the renowned CO dehydrogenases (CODHs), which facilitate the reversible conversion between CO₂ and CO.

Both metallic and oxidized Ni can selectively convert CO₂ to C₁ products at remarkably high rates, while suppressing HER. Ni single-atom catalysts (SACs) exhibit higher reactivity compared to other earth-abundant metals, owing to their moderate CO₂ adsorption capability and d-band proximity to the Fermi level. Ni SACs have been explored as efficient cathode materials for CO₂RR, demonstrating high activity and selectivity.

Moreover, Ni is one of the few metals capable of efficiently catalyzing the reduction of CO₂ into hydrocarbons and alcohols. The uniqueness of Ni-based catalysts in the CO₂RR process can be attributed to the moderate combination between *CO and the Ni-based [catalyst](#), facilitating the activation of CO₂ and the subsequent hydrogenation of *CO, which is a crucial step in hydrocarbon formation.

For example, Ni–Ga alloys were capable of producing ethylene and ethane. Ni phosphides can selectively reduce CO₂ to C₃ and C₄ products (methylglyoxal and 2,3-furandiol, respectively) with a low overpotential (10 mV) and current densities. The unexpected ability of Ni-based

electrocatalysts to promote C–C coupling reactions is noteworthy, considering bulk Ni susceptibility to CO poisoning.

Strong interactions with CO can lead to deactivation or blocking of active sites. Hence, understanding the deactivation mechanisms is crucial. In addition to catalyst design, recent advancements have also focused on improving catalytic systems. Gas diffusion electrodes (GDEs) have been widely employed to directly transport reactant gases to the interface between the catalyst and the electrolyte, enhancing the CO₂ concentration at the catalyst surface and promoting current density.

This review summarizes the recent advancements in efficient Ni-based catalysts and CO₂RR systems. Firstly, the review provides a brief introduction to the reaction mechanisms responsible for the production of C₁ and C₂₊ products.

The main focus is on recent developments specifically related to Ni-based catalysts, including Ni-based complexes, Ni-based single/multi-metallic catalysts, Ni-based compounds, and atomically dispersed catalysts.

Factors that influence catalytic efficiency, such as catalyst surface structure, catalyst size, and surface state, are described in detail. Subsequently, the review outlines strategies concerning catalyst and system design for achieving high Faradaic efficiency (FE) and current density. Finally, the review presents an overview of future opportunities and challenges in the field.
