A group of researchers have made a significant breakthrough which could revolutionize next-generation electronics by enabling non-volatility, large-scale integration, low power consumption, high speed, and high reliability in spintronic devices.

Details of their findings were published in the journal *Physical Review B* on August 25, 2023.

Spintronic devices, represented by magnetic random access memory (MRAM), utilize the magnetization direction of ferromagnetic materials for information storage and rely on spin current, a flow of spin [angular momentum](#), for reading and writing data.

Conventional semiconductor electronics have faced limitations in achieving these qualities.

However, the emergence of three-terminal [spintronic devices](#), which employ separate current paths for writing and reading information, presents a solution with reduced writing errors and increased writing speed. Nevertheless, the challenge of reducing energy consumption during information writing, specifically magnetization switching, remains a critical concern.

A promising method for mitigating [energy consumption](#) during information writing is the utilization of the spin Hall effect, where spin angular momentum ([spin current](#)) flows transversely to the electric current. The challenge lies in identifying materials that exhibit a significant spin Hall effect, a task that has been clouded by a lack of clear guidelines.

"We turned our attention to a unique compound known as cobalt-tin-sulfur ($\text{Co}_3\text{Sn}_2\text{S}_2$), which exhibits ferromagnetic properties at [low temperatures](#) below 177 K (-96°C) and paramagnetic behavior at [room temperature](#)," explains Yong-Chang Lau and Takeshi Seki, both from the Institute for Materials Research (IMR), Tohoku University and co-authors of the study. "Notably, $\text{Co}_3\text{Sn}_2\text{S}_2$ is classified as a topological material and exhibits a remarkable anomalous Hall effect when it transitions to a ferromagnetic state due to its distinctive electronic

structure."

Lau, Seki and colleagues employed theoretical calculations to explore the electronic states of both ferromagnetic and paramagnetic $\text{Co}_3\text{Sn}_2\text{S}_2$, revealing that electron-doping enhances the spin Hall effect. To validate this theoretical prediction, thin films of $\text{Co}_3\text{Sn}_2\text{S}_2$ partially substituted with nickel (Ni) and indium (In) were synthesized. These experiments demonstrated that $\text{Co}_3\text{Sn}_2\text{S}_2$ exhibited the most significant anomalous Hall effect, while $(\text{Co}_2\text{Ni})\text{Sn}_2\text{S}_2$ displayed the most substantial spin Hall effect, aligning closely with the theoretical predictions.

"We uncovered the intricate correlation between the Hall effects, providing a clear path to discovering new spin Hall materials by leveraging existing literature as a guide," adds Seki. "This will hopefully accelerate the development of ultralow-power-consumption spintronic devices, marking a pivotal step toward the future of electronics."
