With the rapid development of industrialization, water pollution is becoming more and more serious. The traditional water treatment method can't effectively remove organic pollutants, so advanced oxidation technology has become a possible solution.

As a potential chemical oxidant, permanganate ( $\text{KMnO}_4$ ) has been widely studied for water decontamination due to its [high efficiency](#), [cost-effectiveness](#) and high stability. However, the poor stability and limited oxidation potential (1.68V) of  $\text{KMnO}_4$  restrict its applications.

To overcome these problems, researchers have tried various innovative approaches to boost the reactivity of  $\text{KMnO}_4$ . Unfortunately, because of the addition of toxic and expensive chemicals and the occurrence of secondary pollution, these routes strongly impede the scientific progress of  $\text{KMnO}_4$  oxidation toward practical applications. In recent years, metal-free carbon materials, especially carbon nanotubes (CNT), have emerged as an attractive additive to  $\text{KMnO}_4$  oxidation due to their environmental friendliness.

CNT is an excellent electron transfer mediator, had been proved as a 'bridge' to facilitate the electron delivery from organic molecules ([electron donor](#)) to persulfate (electron acceptors). This may lead to oxidative decomposition of organic contaminants (OCs), rather than converting from  $\text{KMnO}_4$  to reactive manganese species.

In order to overcome the mass transfer limitation, researchers from Donghua University and Harbin Institute of Technology designed and established a flow-through  $\text{KMnO}_4$ /CNT system.

This study titled "Insights into the electron transfer mechanisms of permanganate activation by [carbon nanotube](#) membrane for enhanced micropollutants degradation" was published online in [Frontiers of Environmental Science & Engineering](#) .

In this study, the research team designed a catalytic CNT membrane for  $\text{KMnO}_4$  activation toward enhanced degradation of micropollutants. The treatment effect of the system was optimized by selecting appropriate operating parameters.

Analysis of experimental data and theoretical calculations revealed the [reaction mechanism](#) and compared the utilization efficiency of permanganate in different systems. In addition, using advanced analytical methods, the degradation pathways of the target substances were revealed and the toxicity of the intermediates was evaluated.

Their results revealed that the flow-through  $\text{KMnO}_4/\text{CNT}$  system outperformed conventional batch reactor. Under optimal conditionals, a  $> 70\%$  removal (equivalent to an oxidation flux of  $2.43 \text{ mmol}/[\text{h}\cdot\text{m}^2]$ ) of  $80 \mu\text{mol}/\text{L}$  sulfamethoxazole (SMX) solution can be achieved at single-pass mode.

The experimental analysis and DFT studies verified that CNT could mediate direct electron transfer from [organic molecules](#) to  $\text{KMnO}_4$ , resulting in a high utilization efficiency of  $\text{KMnO}_4$ .

Furthermore, the  $\text{KMnO}_4/\text{CNT}$  system had outstanding reusability and CNT could maintain a long-lasting reactivity, which served as a green strategy for the remediation of micropollutants in a sustainable manner. This study not only demonstrated the potential application of CNT as electronic media in advanced oxidation processes. Moreover, the system design was robust and efficient, and provided a new solution for green environment remediation.
