

Wheat's long non-coding RNAs unveiled: A leap in understanding grain development

October 2 2023

Comparison of protein-coding genes and lncRNAs in wheat. Credit: Seed Biology

Wheat is a global staple food and plays a pivotal role in the livelihoods of billions of people. Although long non-coding RNAs (lncRNAs) have been recognized as crucial regulators of numerous biological processes, our knowledge of lncRNAs associated with wheat (*Triticum aestivum*) grain development remains minimal.

Seed Biology published an online paper entitled "[A comprehensive atlas of long non-coding RNAs provides insight into grain development in wheat](#)" on 4 September 2023.

To elucidate the landscape of lncRNAs in [wheat](#), the study conducted genome-wide strand-specific RNA sequencing (ssRNA-seq) on grain endosperm at 10 and 15 days after pollination (DAP) and integrated 545 publicly available transcriptome datasets from various developmental stages and tissues. The analysis pipeline was adapted from a previous study with modifications, processed RNA-seq data in three primary steps: mapping, assembly, and filtering.

The results identified 20,893 lncRNAs in wheat. The characterization of these lncRNAs indicated an average transcript length of 900 bp, and were predominantly single exon structure (48%), with significant overlap with long terminal repeat retrotransposons (LTRs, 41.40%).

Compared with [protein-coding genes](#) (PCGs), wheat lncRNAs exhibit shorter transcript lengths, fewer exons, and higher tissue-specific expression than PCGs, and their expression patterns were positively correlated with adjacent PCGs. Furthermore, analyzing the distribution of lncRNAs across the three wheat subgenomes (A, B, and D) revealed that 90.7% of the lncRNAs were exclusive to a single subgenome, suggesting that lncRNAs have different evolutionary trajectories compared with PCGs.

To ensure efficient access to this wealth data, this study developed the

comprehensive database wLNCdb (<http://wheat.cau.edu.cn/wLNCdb>), which provides [various tools](#) to explore wheat lncRNA profiles, including expression patterns, co-expression networks, functional annotations, and [single nucleotide polymorphisms](#) among wheat accessions.

Notably, using wLNCdb, the authors identified the lncRNA TraesLNC1D26001.1, which negatively regulates seed germination as its overexpression delayed wheat [seed germination](#) by upregulating Abscisic acid-insensitive 5 (TaABI5). Moreover, this lncRNA appears to co-express with genes associated with starch and protein biosynthesis in wheat, emphasizing its potential regulatory role in grain development and end-use quality.

In summation, this pioneering study provides a comprehensive map of wheat lncRNAs. The wLNCdb, with its plethora of information and advanced toolset, lays the groundwork for future exploration and analysis of the functions of lncRNAs.

This research not only deepens our understanding of wheat lncRNAs' roles, especially during seed development, but also paves the way for leveraging this knowledge to boost wheat yields and quality in the future.
