Researchers at Lawrence Livermore National Laboratory (LLNL) have developed a modeling tool for assessing the potential use of a nuclear device to defend the planet against catastrophic asteroid impacts.

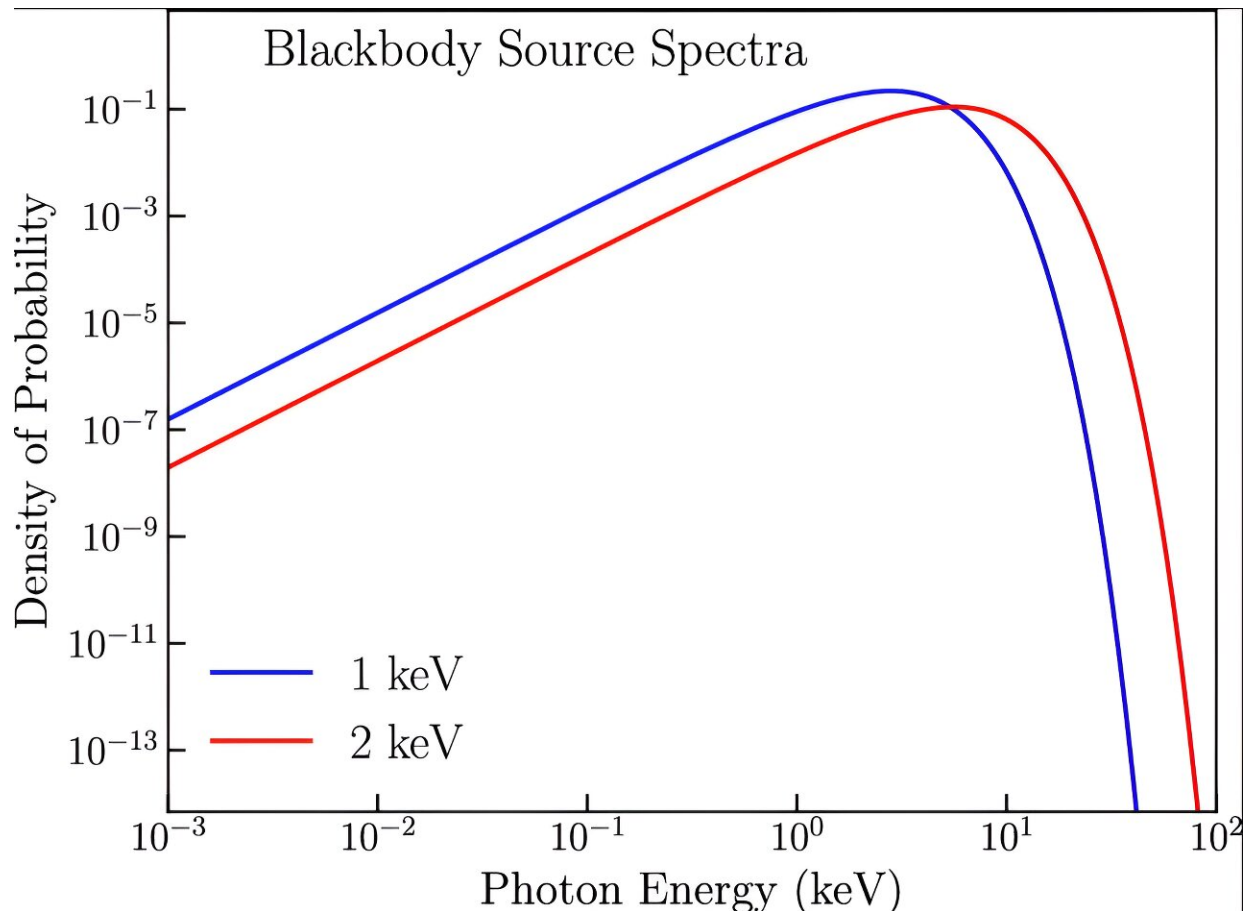

The research, [published today](#) in the *Planetary Science Journal*, introduces a novel approach to simulating the [energy deposition](#) from a nuclear device on an asteroid's surface. This new tool improves our understanding of the nuclear deflection's radiation interactions on the asteroid's surface while opening the door to new research on the shockwave dynamics affecting the inner asteroid.

This model will allow researchers to build upon the insights gained from NASA's recent Double Asteroid Redirection Test (DART) mission, where, in Sept. 2022, a kinetic impactor was deliberately crashed into an asteroid to alter its trajectory. However, with limitations in the mass that can be lifted to space, scientists continue to explore nuclear deflection as a viable alternative to kinetic impact missions.

Nuclear devices have the highest ratio of energy density per unit of mass of any human technology, making them an invaluable tool in mitigating asteroid threats, said LLNL physicist Mary Burkey, who led the research.

"If we have enough warning time, we could potentially launch a nuclear device, sending it millions of miles away to an asteroid that is headed toward Earth," Burkey said. "We would then detonate the device and

either deflect the asteroid, keeping it intact but providing a controlled push away from Earth, or we could disrupt the asteroid, breaking it up into small, fast-moving fragments that would also miss the planet."

Accurate predictions for the effectiveness of nuclear deflection missions rely on sophisticated multiphysics simulations, Burkey said, explaining that LLNL simulation models cover a wide range of physical factors, which makes them complex and computationally demanding.

The paper introduces an efficient and accurate library of X-ray energy deposition functions, developed using the Kull radiation-hydrodynamics code. High-fidelity simulations tracked photons penetrating surfaces of asteroid-like materials such as rock, iron, and ice, while accounting for more complex processes, such as reradiation. The model also considers a diverse set of initial conditions, including different porosities, source spectra, radiation fluences, source durations, and angles of incidence. This comprehensive approach makes the model applicable to a wide range of potential asteroid scenarios.

Should a real planetary defense emergency arise, high-fidelity simulation modeling will be critical in providing [decision-makers](#) with actionable, risk-informed information that could prevent asteroid impact, protect essential infrastructure and save lives, explained Megan Bruck Syal, LLNL's planetary defense project lead.

"While the probability of a large asteroid impact during our lifetime is low, the potential consequences could be devastating," Bruck Syal said.

Led by Burkey, LLNL's research team included co-authors Robert Managan, Nicholas Gentile, Bruck Syal, Kirsten Howley and Joseph Wasem.
