

# Chemical synthesis: New strategy for skeletal editing on pyridines

January 18 2024, by Christina Hoppenbrock

Various strategies for skeletal editing of arenes and heteroarenes. a, Heteroarene skeletal editing through single-atom insertion and deletion that can be used at a late-stage, yet not reported for pyridines. b, Atom swap in arenes is challenging, with existing methods showing limited substrate scope and therefore application to late-stage modification is not possible. c, Our developed strategy through sequential dearomatization, cycloaddition and rearomatizing retrocyclization enabling an atom-pair swap from CN to CC in pyridines. The method is a one-

pot modular approach for pyridine editing with a broad substrate scope that is applicable to late-stage modification. Credit: *Nature Chemistry* (2024). DOI: 10.1038/s41557-023-01428-2

A team from the University of Münster has introduced a strategy for converting carbon–nitrogen atom pairs in a frequently used ring-shaped compound into carbon–carbon atom pairs. The method has potential in the quest for active ingredients for new drugs, for example. The results are [published](#) in *Nature Chemistry*.

In the field of chemistry, so-called skeletal editing is seen as a method suitable for changing ring-shaped structures precisely by swapping [individual atoms](#). A team of researchers led by Prof. Armido Studer from the Institute of Organic Chemistry at the University of Münster has now introduced a new strategy for converting carbon–nitrogen atom pairs in pyridines—a ring-shaped compound frequently used as a synthesis building block—into carbon–carbon atom pairs. The method has potential in the quest for [new drugs](#) and materials that are often based on such molecule rings.

While the [ring structure](#) remains intact in the so-called peripheral functionalization of rings—which involves for example the attachment of groups of atoms—skeletal editing requires the cleavage of robust bonds between carbon atoms or between a carbon atom and another atom within the [ring](#).

"In [organic synthesis](#)," says Studer, "this is considered to be particularly challenging—we can imagine it as a kind of surgical procedure." Up to now, no synthesis strategy was known which could be used to swap complex pyridines by means of skeletal editing.

In this new approach, the team produced benzenes and naphthalenes with [functional groups](#) which are attached precisely to specific positions. Functional groups are groups of atoms that play a decisive role in the properties of a compound.

"The pyridines which we used are inherently inert, making it difficult to modify them," explains post-doc Dr. Qiang Cheng. "We first had to change their specific bonding structure—carrying out so-called dearomatization—in order to obtain significantly more reactive intermediates. The subsequent cycloaddition and rearomatization processes ultimately result in the formation of the skeletal-edited compounds."

Debkanta Bhattacharya, a Ph.D. student on Studer's team, adds, "Now, by using a so-called one-pot procedure, we can introduce synthetically valuable and medically significant functional groups to specific positions on rings."

Chemists speak of a one-pot reaction to describe a synthesis in which the reagents needed react with one another in a single vessel. The reaction sequence's mechanism was theoretically analyzed by Dr. Christian Mück-Lichtenfeld from the Institute of Organic Chemistry.
