Oxidative functionalization of hydrophobic compounds is an important research area from the perspective of effective utilization of natural resources and treatment and reuse of hazardous substances. However, a method that can facilitate such reactions has not been well established.

To resolve this issue, the research team at University of Tsukuba has developed a "catch-and-release" mechanism to oxidize [methane](#) to obtain methanol using an iron complex with a hydrophobic environment near the central metal as a catalyst. Using this catalyst, the team selectively and efficiently oxidized hydrophobic aromatic organic substrates in an aqueous medium under [mild conditions](#). [The study](#) is published in *ACS Catalysis*.

In this reaction, hydrophobic aromatic organic substrates are selectively recognized and trapped in the hydrophobic environment of iron complexes in water and hydrophilic oxidized products formed after [oxidation](#) are released into water. Based on this mechanism, they selectively oxidized hydrophobic aromatic substrates under mild conditions of 50°C in a two-phase system of aqueous solution and organic substrates using the [iron](#) complex.

For benzene oxidation, among others, the turnover number of the involved catalytic reaction exceeded 30,000 in 3 h and 100% phenol selectivity was achieved. Furthermore, the selective two-electron oxidation of anthracene and two-electron oxidation of only [aromatic compounds](#) from mixtures of aliphatic and aromatic compounds, which has been a challenge previously, were realized.

This was achieved using a "recognition-and-release" mechanism, which represents further advancement in the catch-and-release mechanism reported previously. This recognition-and-release mechanism is expected to be an important foundation for the highly efficient and selective chemical transformation of hydrophobic aromatic organic substrates in water.
