

Mitochondrial DNA copy number contributes to growth diversity in allopolyploid fish

April 22 2024

mtDNA copy number and the relationship with body weight. Credit: Zhang, H., et al.

Understanding the relationship between mitochondrial DNA (mtDNA) and animal growth could provide valuable information for selective breeding in aquaculture. However, the complex interactions between genetics and environmental factors often hinders progress in this field.

To that end, a recent study [published](#) in *Reproduction and Breeding* investigated the cross-sectional diameter of skeletal muscle fibers in allotriploid fish with different growth traits.

The researchers selected red crucian carp, common carp and two allotriploid [fish](#) for the study. The allotriploid fish exhibit distinct growth rates and ploidy levels compared to the inbred parental species (red crucian carp and common carp). Deciphering the genetic mechanisms underlying these growth differences holds significant potential for fish breeding.

"Distant hybridization rapidly generates diverse genotypes and phenotypes, offering a rich resource for studying the role of genetic regulation in shaping phenotypes," explains co-corresponding author Li Ren, a researcher at the State Key Laboratory of Developmental Biology of Freshwater Fish at Hunan Normal University.

"Analysis of muscle fiber diameter and mtDNA copy number revealed a positive correlation between individual size and muscle fiber diameter across all fish types. Additionally, a strong correlation emerged between muscle mtDNA copy number and [body weight](#)."

Notably, the researchers observed a decrease in muscle mtDNA copy number within the allotriploid fish during winter. "This decrease likely corresponds with reduced individual activity and [energy expenditure](#) aimed at maintaining body weight, potentially contributing to the observed growth heterosis of allotriploid fish," adds Ren.

Furthermore, the researchers analyzed the [expression levels](#) of three nuclear-regulated mitochondrial genes (tfam, tfb1m, and tfb2m). Interestingly, they found imbalanced allelic expression of tfam and

tfb1m within the allotriploid fish.

Ren highlights the complex relationship between mtDNA, saying, "The copy number and transcriptional efficiency of animal mtDNA are intimately linked not only to the characteristics of the mtDNA genome itself but also to the expression of specific nuclear genes. However, at present, a direct link between these three nuclear-encoded mitochondrial genes and mtDNA copy number variation remains elusive."
