Beginning annually on June 1, hurricane season poses a major threat to Texas coastal communities, causing both physical and financial damage

to the areas they hit. This damage can be staggering; when Hurricane Harvey hit in 2017, it cost Galveston \$132.73 billion in damages. Texas A&M University researchers have collaborated to understand the impacts of storm surge floods before they occur to potentially reduce the level of damage. [Their study was published](#) in *Urban Informatics*.

The researchers have implemented 3D visualization technology to identify the potential outcomes of hurricane flooding before it occurs. According to researchers, [severe weather](#) has been increasing over the last several years due to global climate change. If [severe storms](#) and flooding continue to increase in the future, implementing 3D visualization based on real-time weather forecasts could result in improved safety and less damage-inflicted costs.

The 3D modeling technique also allows researchers to examine the effects of damage-preventing infrastructure, such as the proposed Galveston "Ike Dike," a dike designed to shield Galveston Island from future storm surge and flood events.

Using Galveston Island as an example, researchers used 3D visualization to model the damage that would occur to [residential buildings](#) as a result of hurricanes of varying intensities. They also modeled damage with preventative infrastructure—the "Ike Dike"—in place.

An advantage of 3D visualization over other damage modeling methods is that it allows researchers to model specific buildings, accounting for basements, back entrances, and windows. By identifying a residential building's first-floor elevation level, researchers can predict the physical and financial damage that a hurricane will cause to the specific building.

"3D visualization of hurricanes and storm surges allows us to understand how flooding will impact our coastal communities by allowing us to vividly see how each building and road might be impacted by a given

flood," said Dr. Xinyue Ye, the Harold Adams Endowed Professor of Landscape Architecture and Urban Planning and affiliated faculty member in the Department of Computer Science and Engineering, the Department of Multidisciplinary Engineering, the Department of Geography, and the Section of Visual Computing & Interactive Media.

Faculty collaborators on the project include Dr. David Retchless, associate professor in the Department of Marine and Coastal Environmental Science at Texas A&M University at Galveston, Dr. Galen Newman, professor and head of the Department of Landscape Architecture and Urban Planning and the Nicole and Kevin Youngblood Professor of Residential Land Development at Texas A&M, and Dr. Nick Duffield, the Royce E. Wisenbaker Professor I in the Department of Electrical and Computer Engineering and director of the Texas A&M Institute of Data Science.

Critical information for homeowners

Since 3D visualization highlights the potential damages [hurricane](#) flooding may cause, it can give homeowners a better understanding of what to invest in as far as insurance and preventative infrastructure. This technology also creates an increased community awareness around potential outcomes of hurricanes and flooding.

"Having used Galveston as an example, the next step would be to expand that to other coastal communities in Texas," Ye noted. "In this study, we mainly used residential houses, but we can expand it to other business properties as well."

Effective use of 3D models can protect Texas residents. By implementing this technology on other coastal communities or community buildings, such as schools and stores, researchers can help residents and officials create a plan for [hurricane season](#). As real-time

weather forecasts are implemented into the models, researchers may be able to determine when evacuation is necessary and use this data to alert residents.

"3D visualization serves as a universal language, bridging diverse disciplines and fostering communication between academia and the general public," said Ye, who also serves as the director of the Texas A&M Center for Geospatial Sciences, Applications, and Technology and the founding director of Urban AI Lab at the Texas A&M Institute of Data Science.

Duffield adds that this project shows how the work at the intersection between geospatial data science and visualization can raise awareness for individuals, communities and government on the consequences of extreme weather and make informed planning decisions for responses.

This study combines the expertise of researchers in multiple fields, including computer engineering, landscape architecture, [urban planning](#), geography, and marine and coastal environmental science. The positive impacts of this research highlight the importance of collaboration between computational science and domain-specific disciplines.
