In the lead-up to the 2022 U.S. midterm elections, Arizona's chief election officer Katie Hobbs received far more harassing messages on Twitter than any of her counterparts in other states. More than 30% of all tweets directed at her, along with commentators on her posts, fell into the "most aggressive" category of attacks.

That is a finding from researchers at NYU Tandon School of Engineering, Universidad del Rosario in Colombia, and the University of Murcia in Spain, in a [paper](#) published in *Information Fusion* that examines the phenomenon of online intimidation targeting state election administrators.

The research team used a machine learning model from the Perspective API—a tool developed by Google to identify abusive online comments—to analyze nearly 600,000 tweets mentioning chief state election officials nationwide during the weeks surrounding November 8, 2022.

The tweets were rated based on six attributes: toxicity, severe toxicity, identity attack, insult, profanity, and threat.

Arizona produced the most Twitter activity in the study, representing almost 90% of all collected tweets, and had by far the highest volume of toxic language directed at its top election official, who was also running for governor.

Sentiment analysis revealed these messages exhibited high rates of overt "attacks on the author" and "attacks on commenters," as well as generalized toxicity and inflammatory rhetoric.

"Many of the harassing messages made connections to the 2020 [presidential election](#) and baseless conspiracy theories about electoral fraud," said Damon McCoy, the paper's senior author, a professor of Computer Science and Engineering at NYU Tandon.

McCoy is co-director of Cybersecurity for Democracy, a multi-university research project of the Center for Cybersecurity at NYU Tandon and the Cybersecurity and Privacy Institute at the Northeastern University Khoury College of Computer Sciences that aims to expose

online threats and recommend how to counter them.

To further investigate, the researchers employed entity recognition software to automatically detect references within the hateful messages. It flagged prevalent mentions of "Watergate" and inflammatory phrases like being "at ground zero" for election integrity issues when discussing Arizona.

Clustering analysis based on semantic similarities within the messages also allowed the researchers to identify distinct communities promoting [hate speech](#) and map their interactions.

While [political speech](#) is constitutionally protected, the researchers warn that abuse and intimidation of election workers could have a chilling effect, deterring qualified professionals from overseeing voting and eroding public trust.

"If we want to safeguard democracy, we must find ways to promote civil discourse and protect those ensuring fair elections from harassment and threats," said McCoy.

The study proposes using the data pipeline developed by the researchers to automatically detect abusive accounts and content for faster content moderation. It also calls for clearer policies around harassment of election officials and cultural shifts to uphold democratic norms.
