Researchers at University of Tsukuba have developed a unique technique for synthesizing commonly used polymers, such as polystyrene, using radical polymerization. Here, a remote spark discharge from a Tesla coil, which is a high-voltage, high-frequency generator allows the reaction to proceed without requiring conventional catalysts or polymerization initiators.

This new method provides considerable advancement in synthetic polymer chemistry. The study is [published](#) in the journal *Next Materials*.

Polymers such as polystyrene and acrylic resins are used in various plastic products, including food containers, packaging materials, and thermal cases. Traditionally, metal catalysts and [radical polymerization](#) initiators are used to synthesize these polymers.

This research team has previously developed several polymerization techniques for [conductive polymers](#).

In their latest study, they introduced a novel method for polymer synthesis which involves generating monomer radicals through a remote spark discharge treatment using a Tesla coil, which is a high-voltage, high-frequency generator. These radicals then act as polymerization initiators.

The Tesla coil's capability to generate a powerful discharge without a counter electrode enables the spark discharge treatment to be conducted externally to the reaction vessel. Using this method, the researchers have successfully synthesized high-purity [polystyrene](#) and polymethyl methacrylate (acrylate), both extensively used in food containers.

Moreover, the team has discovered a new method for synthesizing polymers by applying a similar spark discharge treatment to conjugated polymers. They use the "[soliton](#)" generated by the treatment as an

initiator. This innovative approach is a first in synthetic polymer chemistry and opens new avenues for material synthesis using [electromagnetic waves](#).
