

## Studies provide key insights into chloroplast protein import system

August 27 2024

The chloroplast protein import motor plays a pivotal role in biogenesis and homeostasis by driving the translocation of preproteins into chloroplasts. Credit: Designed and generated by the Zhen Yan Lab

Two studies published in the journal *Cell* shed light on the assembly, function and evolutionary diversity of the chloroplast protein import system.

Chloroplasts are fundamental organelles in plant cells that act as the

primary site of photosynthesis to sustain life on Earth. Although <u>chloroplasts</u> have their own genome, most of their proteins are encoded in the nucleus and synthesized as preproteins in the cytosol. These preproteins are subsequently transported across the outer and inner envelope membranes of the chloroplasts.

The translocon machineries, known as the TOC (translocon at the outer chloroplast membrane) and TIC (translocon at the inner chloroplast membrane) complexes, provide the route for preprotein translocation, while energy derived from ATP hydrolysis is required for this process.

An ATPase import motor is believed to provide the pulling force from the stromal side to drive the translocation of preproteins, which is essential for the development and biogenesis of chloroplasts. Despite the fundamental role of the chloroplast import motor, its molecular composition and mode of action remain elusive.

Recently, the Zhen Yan Lab at Westlake University <u>published</u> a study in *Cell* titled "Structural Insights Into the Chloroplast Protein Import in Land Plants." The researchers purified the native Ycf2-FtsHi complex and the TIC complex from Arabidopsis thaliana and determined their high-resolution cryo-EM structures.

They also determined the cryo-EM structure of a translocation intermediate ultracomplex isolated from Pisum sativum at a moderate resolution. Together, these structures provide compelling evidence for the cooperation between the two complexes and offer a valuable look into the translocation mechanism of chloroplast preproteins in land plants.

In the same issue of *Cell*, the Zhen Yan Lab also <u>published</u> a related study titled "Conservation and Specialization of the Ycf2-FtsHi Chloroplast Protein Import Motor in Green Algae."

The researchers isolated the native Ycf2-FtsHi complex from Chlamydomonas and determined its high-resolution cryogenic electron microscopy structures in apo and ATP/AMPPNP bound states. These structures offer detailed insights into the composition and assembly of the Ycf2-FtsHi complex in green algae.

By comparing these findings with those of the Ycf2-FtsHi complex from land plants, this study further illuminates the conservation and specialization of the Ycf2-FtsHi complex across species during evolution.

The two articles contribute to a comprehensive understanding of the conservation, diversity, evolution, and working model of the chloroplast protein import Ycf2-FtsHi complexes. Mastering the structure and mechanism of the chloroplast protein import system is like obtaining the key to unlock the chloroplast gate.

This breakthrough may allow humans to regulate the efficiency of the chloroplast gate for faster passage or to adjust its structure to only permit specific proteins to pass through, thereby optimizing photosynthesis.

This, in turn, could significantly increase the yield of food crops per unit area and greatly enhance the carbon sequestration capacity of plants. Such progress may help address the challenge of food shortages, accelerate the achievement of carbon neutrality goals, and pave the way for a sustainable future for the Earth.
