

Scientists discover giant Rydberg atom molecules

24 June 2009

A group of University of Oklahoma researchers led the scientific journal.
by Dr. James P. Shaffer, Homer L. Dodge

Department of Physics and Astronomy, have discovered giant Rydberg molecules with a bond as large as a red blood cell. Determining how Rydberg molecules interact is important because Rydberg atoms are a key ingredient in atom based quantum computation schemes.

Giant Rydberg [molecules](#) are formed when two Rydberg [atoms](#) interact. A Rydberg atom is an atom that has at least one electron orbiting the nucleus at a very large distance. A giant molecule can form from two Rydberg atoms when they are in close proximity to one another because fluctuations of the electron orbiting the nucleus can create an electric field at the position of the other Rydberg atom and vice versa to attract the atoms to each other.

An additional electric field can change the orbit of the electrons and lead to a change in the forces acting between the Rydberg atoms. The ability to change the orbit of the electron with an electric field is what makes it possible to control the properties of the molecule, such as [binding energy](#) and vibrational frequencies. Applying an [electric field](#) to tailor the properties of these types of molecules is a unique property.

The characteristics of the macroscopic molecules make them ideal candidates for probing quantum gases, properties of the electromagnetic field, and determining how Rydberg molecules interact. Shaffer says an understanding of these problems will bring us closer to a new generation of quantum mechanical devices that meld the best properties of isolated atomic systems with advances in microelectronic fabrication and materials science.

The research performed by Shaffer, K.R. Overstreet, A. Schwettmann, J. Tallant, and D. Booth is reported in the advanced online version (June) of [Nature Physics](#) and in the July issue of
