

China rice laced with heavy metals: report

February 16 2011

Up to 10 percent of rice grown in China is contaminated with harmful heavy metals but little has been done to highlight the possible public health risks, a report said.

This week's edition of the New Century magazine cited studies showing that large amounts of Chinese [rice](#) have been tainted with [heavy metals](#) like cadmium due to years of pollution stemming from the nation's rapid economic growth.

"During China's fast-paced industrialisation, activities such as mining have sprung up everywhere, releasing into the environment [chemical elements](#) like cadmium, arsenic, mercury and other harmful heavy metals," the report said.

"These harmful heavy metals have spread through the air and water, polluting a rather large area of China's land... a complete chain of food contamination has existed for years."

The report cited academic studies since 2007 focusing on several rural villages in southern [China](#) near mines and industrial areas where health problems such as bone diseases have emerged, mostly among the elderly.

Pan Genxing, a scientist who carried out some of the key research cited in the report, said the percentage of tainted rice was even higher in some specific localities.

"In areas with acidic soil that are known to be badly polluted, we have

found that up to 60 percent of the rice samples gathered there surpass cadmium standards," Pan, a scientist with Nanjing Agricultural University, told AFP.

However he added that while cadmium levels were sometimes five times higher than government standards, the problem represented a "potential health risk" rather than dangerous "acute toxicity".

Most at risk from high cadmium levels were subsistence farmers in polluted areas who mainly live on the rice they grow, Pan said.

Of the major grains, rice has the strongest ability to absorb [cadmium](#), which often seeps into water used for irrigation near mines, especially those that extract lead, tin and copper, the report said.

The magazine report said, however, that no major investigations into the possible public health impact have been carried out.

Rice, which is widely grown in south China, is the nation's staple grain with about 200 million tonnes produced annually, the report said.

Food safety is a major problem in China, where scares regularly emerge including recent scandals involving contaminated red wine, bleached mushrooms, fake tofu and recycled cooking oil.

In 2008, at least six children died and around 300,000 fell sick after consuming powdered milk laced with the industrial chemical melamine, which was added to make products appear higher in protein.

Rapid industrialisation over the past 30 years helped China become the world's second-largest economy last year.

But the focus on growth, combined with lax environmental protection,

has saddled the country with some of the world's worst water and air pollution.
