

Artificial magnetic bacteria "turn" food into natural drugs

12 May 2014, by José Manuel Domínguez-Vera

Artificial magnetic bacteria are probiotic bacteria surrounded by thousands of magnetic iron oxide nanoparticles. The bacteria are living magnets that align with an external magnetic field. They may have many applications as magnetic drugs.

Scientists from the University of Granada have successfully created magnetic bacteria that could be added to foodstuffs and could, after ingestion, help diagnose diseases of the digestive system like stomach cancer. These important findings constitute the first use of a food as a natural drug and aid in diagnosing an illness, anywhere in the world.

The researchers—members of Bionanomet, the Metallic Bionanoparticle research group of the Department of Inorganic Chemistry and the Institute of Biotechnology of the University of Granada—have conducted this research in collaboration with BIOSEARCH SA, a private company. Their results have been published in the latest issue of *Advanced Functional Materials*.

To design these magnetic bacteria, the researchers looked to Nature. They tried to copy

magnetobacteria, which naturally produce very limited numbers of internal magnets that, essentially, provide them with a means of orienting themselves as if they possessed an internal compass.

Biomedical applications

These artificial magnetic bacteria could have [biomedical applications](#) in magnetic resonance imaging—to facilitate diagnosis—or in heating malign cells through magnetic hypothermia and, thus, curing diseases like cancer.

This new technology—patented by BIOSEARCH SA—is still only in an experimental phase but it will facilitate the use of these [probiotic bacteria](#), common in food, to diagnose and treat tumours and as an edible iron supplement.
