

Modern logging techniques benefit rainforest wildlife

27 February 2015

New research has highlighted the value of a modern logging technique for maintaining biodiversity in tropical forests that are used for timber production.

using reduced-impact logging. *Journal of Applied Ecology*. doi: 10.1111/1365-2664.12391

Researchers at the Durrell Institute of Conservation and Ecology (DICE) at the University of Kent say that with over 4 million km² of tropical forests harvested for [timber](#) worldwide, improving the way logging impacts on [wildlife](#) is essential for global biodiversity conservation.

Provided by University of Kent

Members of DICE conducted the most comprehensive study of Reduced-Impact Logging (RIL) to date, surveying wildlife communities over a five-year period before and after timber harvesting.

The research team, comprising Dr Jake Bicknell, Dr Matthew Struebig and Dr Zoe Davies, discovered that RIL had very little effect on the birds, bats and large mammals in the rainforests of Central Guyana. In fact, they found that the natural rates of change in the wildlife communities were greater than those resulting from this type of modern, best-practice logging technique.

Now the researchers hope the new evidence, showing the benefits of adopting RIL over conventional logging, will encourage governments and timber companies to make the switch in their timber industry practices.

Dr Bicknell said the research demonstrated that RIL is a 'cost-effective option' that will ensure the long-term sustainability of biodiversity-rich [tropical forests](#) around the world. It is better for wildlife because it 'minimises collateral damage to unlogged trees in the forest, and reduces gaps in the forest canopy which are associated with conventional logging'.
