High-Tc superconductivity found under high pressure
24 June 2015

Figure 1. The \((\text{NH}_3)_y\text{Cs}_{0.4}\text{FeSe}\) sample prepared by liquid ammonia technique.

Drastic enhancement of superconducting transition temperature \((T_c)\) can be induced by placing materials under high pressure, state Yoshihiro Kubozono and his team at Okayama University.

In previous studies, Metal-intercalated FeSe's prepared using liquid ammonia technique showed very high \(T_c\) of 30 - 45 K. With an increase in FeSe plane spacing \((d)\), the \(T_c\) increased rapidly, showing that the increase in two-dimensionality leads to the higher \(T_c\).

Until recently, the limit of \(T_c\) was recognized as 45 K, because of a saturation of \(T_c - d\) plot. Sun et al. conducted a study during which, in the pressure-induced high-Tc superconducting phase for two metal doped FeSe materials \((\text{Tl}_{0.6}\text{Rb}_{0.4}\text{Fe}_{1.67}\text{Se}_2\) and \(\text{K}_{0.8}\text{Fe}_{1.7}\text{Se}_2)\), the maximum \(T_c\) reached 48 K. However, such behavior has rarely been reported because it is extremely difficult to conduct the necessary experiments.

In a recent study, Kubozono and his team applied high-pressure to ammoniated Cs doped FeSe \((\text{NH}_3)_y\text{Cs}_{0.4}\text{FeSe})\) material. They measured the temperature dependence of resistance under pressures of between 0 – 41 GPa.

The \(T_c\) of \((\text{NH}_3)_y\text{Cs}_{0.4}\text{FeSe}\) (31 K at ambient pressure) gradually decreased with increasing pressure, and no superconductivity was observed down to 4.2 K at 11 - 13 GPa. The superconductivity reemerged rapidly above 13 GPa, and a dome-like pressure-dependence of \(T_c\) was found at 15 - 41 GPa. The maximum \(T_c\) reached 49 K at 21 GPa.

The emergence of high-Tc phase under high pressure may be characteristic for all metal doped FeSe materials, which may provide a hint for realizing higher \(T_c\) superconductors in two-dimensional layered materials in future.
