

# Some chemicals less damaging to ozone can degrade to long-lived greenhouse gas

3 November 2015

Some substitutes for ozone-damaging chemicals being phased out worldwide under international agreements are themselves potent greenhouse gases and contribute to warming. Now, a new study published Nov. 2 in *Geophysical Research Letters*, a publication of the American Geophysical Union, shows for the first time how some of those replacement chemicals can break down in the atmosphere to form a greenhouse gas that can persist for millennia, much longer than the substitute chemicals themselves.

Specifically, when some chemicals widely used as refrigerants break down in the stratosphere—a layer in the middle atmosphere—under some conditions, they can form a [potent greenhouse gas](#) that lasts for up to 50,000 years, according to scientists from the Cooperative Institute for Research in Environmental Sciences (CIRES) at the University of Colorado Boulder and the NOAA Earth System Research Laboratory (ESRL) in Boulder.

"This compound, carbon tetrafluoride or CF<sub>4</sub>, essentially lasts forever because there aren't any known removal mechanisms in the atmosphere," said James Burkholder, a research chemist at NOAA ESRL and lead author of the study.

Burkholder's colleague Aaron Jubb, a CIRES scientist working at NOAA ESRL and now at Oak Ridge National Laboratory, did the laboratory work showing how CF<sub>4</sub> can be made from some halocarbons, chemicals that include hydrofluorocarbons (HFCs) and hydrochlorofluorocarbons (HCFCs) and are substitutes for the more ozone-damaging chemicals that have largely been phased out. Jubb started with trifluoroacetyl fluoride—a compound produced in the atmosphere when some halocarbons breaks down—exposed it to short-wavelength UV radiation, and looked at the reaction products that formed. CF<sub>4</sub> was one of those breakdown products.

The amount of CF<sub>4</sub> produced by this photochemical process was shown to be a small fraction of atmospheric CF<sub>4</sub>; industrial sources are much larger emitters of CF<sub>4</sub>. Still, identifying this particular source of such a potent and lasting [greenhouse gas](#) is important, particularly since its production could continue to grow depending on which "parent" products are used by industry.

"We really need to understand the chemistry of the compounds we use," Jubb said. "Even as we move towards shorter-lived halocarbons for industrial use, during atmospheric degradation they can produce a long-lived atmospheric effect."

This work was supported in part by NOAA's Atmospheric Chemistry, Carbon Cycle, and Climate (AC4) Program and NASA's Atmospheric Composition Program.
