(Phys.org)—Scientists have used sunlight to turn seawater ( $\text{H}_2\text{O}$ ) into hydrogen peroxide ( $\text{H}_2\text{O}_2$ ), which can then be used in fuel cells to generate electricity. It is the first photocatalytic method of  $\text{H}_2\text{O}_2$  production that achieves a high enough efficiency so that the  $\text{H}_2\text{O}_2$  can be used in a fuel cell.

The researchers, led by Shunichi Fukuzumi at Osaka University, have published a paper on the new method of the photocatalytic production of [hydrogen peroxide](#) in a recent issue of *Nature Communications*.

"The most earth-abundant resource, seawater, is utilized to produce a solar fuel that is  $\text{H}_2\text{O}_2$ ," Fukuzumi told *Phys.org*.

The biggest advantage of using liquid  $\text{H}_2\text{O}_2$  instead of gaseous hydrogen ( $\text{H}_2$ ), as most fuel cells today use, is that the liquid form is much easier to store at high densities. Typically,  $\text{H}_2$  gas must be either highly compressed, or in certain cases, cooled to its [liquid state](#) at cryogenic temperatures. In contrast, liquid  $\text{H}_2\text{O}_2$  can be stored and transported

at high densities much more easily and safely.

The problem is that that, until now, there has been no efficient photocatalytic method of producing liquid  $\text{H}_2\text{O}_2$ . (There are ways to produce  $\text{H}_2\text{O}_2$  that don't use sunlight, but they require so much energy that they are not practical for use in a method whose goal is to produce energy.)

In the new study, the researchers developed a new photoelectrochemical cell, which is basically a solar cell that produces  $\text{H}_2\text{O}_2$ . When sunlight illuminates the photocatalyst, the photocatalyst absorbs photons and uses the energy to initiate chemical reactions (seawater oxidation and the reduction of  $\text{O}_2$ ) in a way that ultimately produces  $\text{H}_2\text{O}_2$ .

After illuminating the cell for 24 hours, the concentration of  $\text{H}_2\text{O}_2$  in the seawater reached about 48 mM, which greatly exceeds previous reported values of about 2 mM in pure water. Investigating the reason for this big difference, the researchers found that the negatively charged chlorine in seawater is mainly responsible for enhancing the photocatalytic activity and yielding the higher concentration.

Overall, the system has a total solar-to-electricity [efficiency](#) of 0.28%. (The photocatalytic production of  $\text{H}_2\text{O}_2$  from seawater has an efficiency of 0.55%, and the [fuel cell](#) has an efficiency of 50%.)

Although the total efficiency compares favorably to that of some other solar-to-electricity sources, such as switchgrass (0.2%), it is still much lower than the efficiency of conventional solar [cells](#). The researchers expect that the efficiency can be improved in the future by using better materials in the photoelectrochemical cell, and they also plan to find methods to reduce the cost of production.

"In the future, we plan to work on developing a method for the low-cost, large-scale production of H<sub>2</sub>O<sub>2</sub> from [seawater](#)," Fukuzumi said. "This may replace the current high-cost production of H<sub>2</sub>O<sub>2</sub> from H<sub>2</sub> (from mainly natural gas) and O<sub>2</sub>."
