

A wave's 'sweet spot' revealed

29 June 2017

For surfers, finding the "sweet spot," the most powerful part of the wave, is part of the thrill and the challenge.

Scripps Institution of Oceanography at the University of California postdoctoral researcher Nick Pizzo has found the exact location on the wave where a surfer gains the greatest speed to get the best ride.

Published this month online in the *Journal of Fluid Mechanics*, Pizzo applied principles of physics at the ocean's surface—where air and water meet—to study how energy is transferred from the underlying wave to a particle on the surface, in this case, a surfer.

"Based upon the speed and geometry of the wave, you can determine the conditions to surf a wave and also where on the wave the maximum acceleration, or '[sweet spot](#),' will be located," said Pizzo, the author of the new paper and an avid surfer.

Pizzo and fellow researchers in the Air-Sea Interaction Laboratory at the Scripps Marine Physical Laboratory and Physical Oceanography

Research Division are studying the mass, momentum, and energy exchanged between the atmosphere and ocean due to breaking waves, to help improve our understanding of weather and [climate](#).

As a wave breaks at the ocean surface, currents are generated and water droplets in the form of sea spray are ejected from the ocean into the atmosphere. These small-scale processes are critical pieces of information to improve weather and climate models to better forecast major storm events and the future climate.

"The study was motivated by important scientific questions that lead to a better description of the upper ocean to be used in weather and [climate models](#)," said Pizzo. "By studying the acceleration of a theoretical surfer on a wave, we can provide a better description of the currents generated by breaking waves, leading to an improved understanding of the momentum and energy budget between the atmosphere and [ocean](#)."

Breaking waves, like those surfers ride close to shore, are infrequent in the world's oceans. However, according to Pizzo, they are nonetheless fundamental to weather prediction, where, for example, storms and hurricanes are strongly influenced by the physical processes generated by breaking waves, as well as the longer-term evolution of the climate.

"We need to understand the little things to get the big picture," he added.

So, where is the "sweet spot?" Right inside the curl of the breaking wave.
