Ultrahigh-resolution insights into vegetation dynamics and terrestrial evaporation

21 March 2018

The availability of high-resolution data collected by miniaturized satellites heralds a turning point in Earth and environmental sensing from space. The advent of small, specialized satellites called CubeSats are transforming our ability to monitor the Earth's surface and the impact of human activity on the planet. Scientists at KAUST are pioneering research techniques based on CubeSat data and are excited about the potential of these satellites, particularly for the fields of hydrology and precision agriculture.

Traditional satellite data used for research, collected predominantly by government space agencies, presents certain limitations. Generally, either the data provides high spatial resolutions occasionally—detailed images taken every two weeks—or the data provides low spatial resolution frequently. In the latter scenario, significant details can be missed. CubeSats are changing this paradigm, collecting meter-scale spatial detail over Earth's terrestrial surfaces every day.

"I certainly didn't expect these constraints to be lifted any time soon," says hydrologist and remote-sensing specialist, Matthew McCabe, of KAUST. "Normally, satellite design takes years—researching and developing sensors, negotiating with a government space agency and funding bodies—before possibly seeing your mission chosen for launch. Then, there's the chance that something could go wrong upon launch or deployment or that you simply don't get the data you need."

McCabe's team recently launched a project in line with the Saudi Arabian government's Vision 2030 that uses data from CubeSats and other satellites to help monitor water and food security issues. With agriculture using vast quantities of the Kingdom's limited freshwater supplies, the team will use these satellite data to monitor crop health and irrigation rates to build up a clear picture of the country's water use. This work will help guide future policies in water security.

Similarly, the status of global food security could be analyzed using data from CubeSats. As McCabe's team recently demonstrated, it is now possible to retrieve high-quality imagery of individual fields daily, down to a resolution of three meters. From these, machine learning techniques can assess the health and condition of individual crops using measurements, such as leaf-area index and transpiration rates. This will enable more accurate predictions of potential yields and can verify when and where problems start, allowing farmers to take appropriate action.

"CubeSat technology also allows us to interrogate..."
data to find out which crops are being grown where," adds McCabe. "In African countries, for example, there are few records showing what each farmer grows on their small piece of land. This information could pass into globally relevant databases to help tackle food security issues by tracking supply."

CubeSats are largely being built and launched by commercial companies at present, although space agencies, such as NASA and ESA, are also funding some CubeSat and nano-sat initiatives.

"I've developed a strong collaboration with a CubeSat company called Planet," says McCabe. "Data from their CubeSat missions are available to scientists in all different fields for analysis—it's an incredible resource. Although most CubeSats don't carry expensive, research-grade components, meaning calibration can be a problem, we're working on a range of innovative machine learning and modeling techniques that provide research quality data for Earth observation."

McCabe sees the potential of CubeSats in providing new insights across environmental sciences but also in providing a platform for the demonstration of novel sensors and technologies in space. By harnessing these emerging systems, strategies that address some of the major global challenges in food, water and environment could soon be implemented.
