Colorado State University polymer chemists have taken another step toward a future of high-performance, biorenewable, biodegradable plastics.

Publishing in *Nature Communications*, the team led by Professor of Chemistry Eugene Chen describes [chemical](#) synthesis of a polymer called bacterial poly(3-hydroxybutyrate) – or P₃HB. The compound shows early promise as a substitute for petroleum plastics in major industrial uses.

P₃HB is a biomaterial, typically produced by bacteria, algae and other microorganisms, and is used in some biomedical [applications](#). Its high production costs and limited volumes render the material impractical in more widespread commodity applications, however.

The team, which includes the paper's first author and research scientist Xiaoyan Tang, used a starting material called succinate, an ester form of succinic acid. This acid is produced via fermentation of glucose and is first on the U.S. Department of Energy's list of top 12 biomass-derived compounds best positioned to replace petroleum-derived chemicals.

The researchers' new [chemical synthesis](#) route produces P₃HB that's similar in performance to bacterial P₃HB, but their route is faster and offers potential for larger-scale, cost-effective production for commodity plastic applications. This new route is enabled by a class of powerful new catalysts they have designed and synthesized. They have filed a provisional patent through CSU Ventures for the new technology.
