

# **Unjamming the genome after DNA damage: A gene regulatory multi-tool has yet another function**

April 5 2019, by Sam Sholtis

---

Ccr4-Not to the rescue. A) Ccr4-Not complex associates with RNA polymerase II (RNAPII) as it travels along a strand of DNA producing RNA. B) When RNAPII becomes stuck due to DNA damage, Ccr4-Not recruits factors that mark RNAPII with a small signaling molecule called ubiquitin. C) Ubiquitylation triggers degradation of RNAPII, allowing DNA repair enzymes to repair the damage and restore gene expression. Credit: Reese Laboratory, Penn State

A protein complex that is involved in nearly every step in the regulatory control of gene expression in cells has now been shown also to play a key role in clearing potential traffic jams in the production of RNA.

RNA polymerase II (RNAPII)—the enzyme that produces RNA from a DNA template—can become stuck due to damage to the DNA template, and these jams must be cleared to restore gene expression and normal cell function. New research shows that the master regulatory complex, "Ccr4-Not," performs this task, associating with RNAPII during the transcription of RNA from DNA and marking RNAPII for degradation when it becomes stuck, allowing the DNA to be repaired and normal cell function to resume.

A paper describing the research by Penn State scientists appears online in the journal *Genes & Development* on April 4, 2019.

"Normal cellular functions rely on what is sometimes called the 'central dogma of biology,'" said Joseph C. Reese, professor of biochemistry and molecular biology and member of the Center for Eukaryotic Gene Regulation at Penn State. "Genes in DNA are transcribed into RNA, which are in turn translated into proteins, which carry out the function of the cell. This is a highly orchestrated process and the precise control of

[gene expression](#) and protein turnover determines cellular functions.

"The Ccr4-Not complex is involved in nearly every step of this process from start to finish. Our new research shows that this complex has an additional function that helps maintain normal cellular function when something goes wrong during transcription."

During the transcription of RNA from DNA, RNAPII—itsself a large complex made up of multiple protein subunits—travels along the strand of DNA reading the ATCG sequence and producing a complementary strand of RNA. If the RNAPII encounters DNA damage, which can be caused by UV radiation and other sources, it can become stuck and prevent trailing polymerases from completing transcription of the gene, similar to how a stalled car prevents traffic behind it from flowing. If this jam cannot be cleared, multiple RNAPIIs transcribing the same gene can start to pile up in a sort of traffic jam preventing the DNA from being repaired and hampering cell function.

"The clearing of stuck RNAPII is an essential process for normal cell function," said Reese. "Defects in this pathway have been associated with a number of diseases and [human syndromes](#), such as Cockayne syndrome—a neurodegenerative disorder that results in growth failure, neurological developmental defects, and sensitivity to UV light."

The researchers used genetic methods and reconstitution biochemistry—a method whereby purified components of a cellular process can be added, taken away, and mixed in a precisely controlled manner to identify exactly how they [function](#)—to show that Ccr4-Not recruits factors that mark RNAPII with a small signaling molecule called ubiquitin. Attachment of ubiquitin to RNAPII triggers other cellular components to degrade the enzyme, clearing the jam.

"Previous studies had implicated Ccr4-Not in helping cells cope with

DNA damage," said Reese. "Mutating members of the Ccr4-Not complex makes [cells](#) more sensitive to agents that damage the genome, but because Ccr4-Not is involved in so many aspects of gene regulation it wasn't clear until now what its precise role was. The fact that Ccr4-Not recruited the destruction machinery to RNAPII was a surprising result, and suggests it acts as a tow truck to remove traffic jams throughout the genome. "
