

# Urban growth, heat islands, humidity, climate change: Costs multiply in tropical cities

10 September 2019, by Taha Chaiechi And Silvia Tavares

Some [60% of the planet's expected urban area by 2030](#) is yet to be built. This forecast highlights how rapidly the world's people are becoming urban. Cities now occupy about 2% of the world's land area, but are home to about [55% of the world's people](#) and generate more than [70% of global GDP](#), plus the associated [greenhouse gas emissions](#).

So what does this mean for people who live in the tropical zones, where [40% of the world's population lives](#)? On current trends, this figure will rise to 50% by 2050. With [tropical economies growing some 20% faster](#) than the rest of the world, the result is a swift expansion of tropical cities.

The populations of these growing tropical cities

already experience high temperatures made worse by high humidity. This means they are highly vulnerable to [extreme heat events](#) as a result of climate change.

For example, extremely hot weather overwhelmed Cairns last summer. By December 3 2018, the [city](#) had recorded temperatures above 35°C nine days in a row. Four consecutive days were above 40°C.

For our research, temperature and humidity sensors were strategically placed in the Cairns CBD to represent people's experience of weather at street level. These recorded temperatures consistently higher than the Bureau of Meteorology (BoM) recordings, reaching 45°C at some points.

## Local effects magnify heatwave impacts

Urban environments in general are hotter than non-urbanized surroundings that are covered by vegetation. The trapping of [heat](#) in cities, known as the [urban heat island](#) effect, has impacts on human health, animal life, social events, tourism, water availability and business performance.

The [urban heat island effect](#) intensifies the impacts of increasing heatwaves on cities as a result of climate change.

But it is important to remember that other local factors also influence these impacts. These include the scale, shape, materials, composition and growth of the built environment in a particular location and its surrounding areas.

The differences between the BoM data recorded at Cairns airport and the inner-city recordings show the impacts of urban expansion patterns, built form and choice of materials in tropical cities.

The linear layout of Cairns has, on one hand, enabled the formation of attractive places for commercial activities. As these activity centers evolve into focal points of urban life, they in turn influence all sorts of socioeconomic parameters.

On the other hand, the form the built environment takes changes the patterns of wind, sun and shade. These changes alter the urban microclimate by trapping heat and slowing or channeling air movements.

**Shifting the focus to the tropics**

To date, a large body of research has explored the undesired consequences of climate change and urban heat islands. However, the focus has been on capital and metropolitan cities with [humid continental climates](#). Not many studies have looked at the economic and social impacts in the tropical context, where hot and humid conditions create extra heat stress.

Add the combined effects of climate change and urban heat islands and what are the socio-economic consequences of heatwaves in a tropical city like Cairns? We see that climate change adds another dimension to the relationship between cities, economic growth and development.

This presents a huge opportunity to start thinking about building cities that are not superficially greenwashed, but which instead tackle pressing issues such as climate variability and create sustainable business and social destinations.

In cold climates, heatwaves and urban heat islands are not necessarily undesired, but their negative impacts are more obvious and harmful in warmer climates. And these harmful impacts of heatwaves on our economy, environment and society are on the rise.

We have scientific evidence of the increasing length, frequency and intensity of heatwaves. The number of record hot days in Australia has [doubled in the past five decades](#).

**Cairns Regional**

ON Mean ON Range ON Models

**Changes across seasons for regions**

Long-term regional changes in relation to reference period (1986-2005) across seasons

**Changes over time for regions**

Long-term regional changes in relation to reference period (1986-2005) over time

**What are the costs of heatwaves?**

Increased exposure to heatwaves amplifies the adverse economic impacts on industries that are reliant on the health of their outdoor workers. This is in addition to the extreme heat-related fatalities and health-care costs of heatwave-related medical emergencies. As a [PwC report to the Commonwealth](#) on extreme heat events stated: "Heatwaves kill more Australians than any other natural disaster. They have received far less [public attention](#) than cyclones, floods or bushfires—they are private, silent deaths, which only hit the media when morgues reach capacity or infrastructure fails."

Heat also has direct impacts on economic production. A [2010 study](#) found a 1°C increase resulted in a 2.4% reduction in non-agricultural production and a 0.1% reduction in agricultural production in 28 Caribbean-basin countries. Another [study in 2012](#) found an 8% weekly loss of production when the temperature exceeded 32°C for six days in a row.

The 2017 [Farm performance and climate](#) report by the [Australian Bureau of Agricultural and Resource Economics and Sciences \(ABARES\)](#) states: "The recent changes in [climate](#) have had a significant negative effect on the productivity of Australian cropping farms, particularly in southwestern Australia and southeastern Australia."

It's not just farming that is vulnerable. A [Victorian government report](#) report this year estimated an extreme [heatwave](#) event costs the state's construction sector A\$103 million. The impact of heatwaves on the city of Melbourne's economy is estimated at A\$52.9 million a year on average.

According to this report, economic costs increase exponentially as the severity of heatwaves increases. This has obvious implications for cities in tropical regions.

As the next step in [our research](#), we are examining the relationship between local urban features, urban heat islands, the resulting city temperatures and their direct and indirect (spillover) effects on local and regional economic activities.
