Extreme weather could bring next recession
17 February 2020

For example, excessive high temperatures, like those experienced in the United States and Europe last summer, can be deadly. Not only do they disrupt agriculture, harm human health and stunt economic growth, they also can overwhelm and shut down vast parts of energy delivery, as they did in Northern California when PG&E shut down delivery during fires and weather that could trigger fire. Extreme weather can also threaten other services such as water delivery and transportation, which in turn affects businesses, families and entire cities and regions, sometimes permanently. All of this strains local and broader economies.

"Despite these obvious risks, investors and asset managers have been conspicuously slow to connect physical climate risk to company market valuations," Griffin said in his article.

"Loss of property is what grabs all the headlines, but how are businesses coping? Threats to businesses could disrupt the entire economic system."

Climate-vulnerable locations also factor into risk for energy markets. In the United States, U.S. oil refining is located on the Gulf Coast, an area exposed to sea-level rise and intense storms. Oil refining in Benicia and Richmond, in Northern California, can be exposed to coastal flooding. Energy companies' transmission infrastructure is located in arid areas, increasing risk of damage, such as the destruction from recent wildfires in California. In addition, it is not clear insurance will be available to cover such risks. Add to those risks, Griffin said, "litigation, sanctions and even loss of business from the property destroyed.

"The climate litigation risk already priced into energy stocks (after, for example, a protracted ExxonMobil court case in the 1990s) would prove insufficient."

Extreme weather climate risk, in summary, is hard to predict.
"While proprietary climate risk models may help some firms and organizations better understand future conditions attributable to climate change, extreme weather risk is still highly problematic from a risk estimation standpoint," he concluded in the article.

"This is because with climate change, the patterns of the past are no guide to the future, whether it be one year, five years or 20 years out. Investors may also normalize extreme weather impacts over time, discounting their future importance."
