A research team led by Prof. Qian Peiyuan, Head and Chair Professor

from the Hong Kong University of Science and Technology (HKUST)'s Department of Ocean Science and David von Hansemann Professor of Science, has published their cutting-edge findings of symbiotic mechanisms of a deep-sea vent snail (*Gigantopelta aegis*) in the scientific journal *Nature Communications*. They discovered that the *Gigantopelta* snail houses both sulfur-oxidizing bacteria and methane-oxidizing bacteria inside its esophageal gland cells (part of the digestive system) as endosymbionts. By decoding the genomes of both snail host and the two symbionts, Prof. Qian's team disclosed a novel dual symbiosis system and molecular adaptation to the extreme environment, gaining a new understanding of the origin of life on Earth.

Deep-sea hydrothermal vents are characterized by extremely high hydrostatic pressures and darkness, and they can release fluids overheated by the Earth's crust, with concentrated toxic heavy metals and [chemical substances](#). These characteristics make hydrothermal vents one of the most uniquely extreme environments on our planet. In addition, the deep-sea hydrothermal [vent environment](#) is very similar to the Earth's early environment, when life began to form. Unlike most ecosystems relying on photosynthesis-derived nutrients, fauna living in vents depend on chemosynthetic microbes that can utilize [chemical energy](#) to synthesize organic compounds, supporting dense and unique macro-organisms living there. However, how the organisms thrive and adapt to such an extreme environment remains a complex puzzle.

In April and May 2019, Prof. Qian's team undertook a deep-sea research expedition and explored Longqi vent field on the Southwest Indian Ridge with a remotely operated vehicle. They found a [dominant species](#), *Gigantopelta* snails, at the sea floor (approximate 2800 m depth). Prof. Qian's team discovered two types of symbiotic [bacteria](#) with dramatically different morphologies that live inside the esophageal gland cells of *Gigantopelta* snails, which was further identified as one sulfur-oxidizing bacteria and one methane-oxidizing bacteria.

The team further decoded the genomes of the *Gigantopelta* snail, sulfur-oxidizing bacteria and methane-oxidizing bacteria, unveiling a novel dual

symbiosis system highly versatile in utilizing chemical energy for nutrient synthesis. The sulfur-oxidizing bacteria can utilize the chemical energy from hydrogen, hydrogen sulfide, sulfate, sulfite and thiosulfate, while the methane-oxidizing bacteria can utilize hydrogen and methane. From the host side, there are more copies of pattern recognition receptors in *Gigantopelta* genome, and they are specifically expressed in the symbiotic organ, which help *Gigantopelta* recognize and maintain a dual symbiosis system. *Gigantopelta* snails adopt a mutualistic metabolic relationship among multiple symbiotic partners and thus flourish in this vent ecosystem. These findings not only enable us to gain a better understanding of how animals thrive in such extreme environment, but also shed light on how such animals cope with microbes in a highly specialized way.
